

2.1

Bisection Method

* IVT: if $f(a)$ and $f(b)$ are opposites in sign, then there is a $c \in [a, b]$, such that $f(c) = 0$ $f(a) = +ve \rightarrow f(b) = -ve$

* Finding the approximate value of x for which $f(x) = y = 0$

* Finding approximate solution of a function * We try to decrease the interval by dividing it by 2 each time till we find c

Bisection Technique The first technique, based on the Intermediate Value Theorem, is called the Bisection, or Binary-search, method. Suppose f is a continuous function defined on the interval $[a, b]$, with $f(a)$ and $f(b)$ of opposite sign.

The Intermediate Value Theorem implies that a number p exists in (a, b) with $f(p) = 0$.

Although the procedure will work when there is more than one root in the interval (a, b) , we assume for simplicity that the root in this interval is unique. The method calls for a repeated halving (or bisecting) of subintervals of $[a, b]$ and, at each step, locating the half containing p . To begin, set $a_1 = a$ and $b_1 = b$ and let p_1 be the midpoint of $[a, b]$, that is.

$$P_1 = a_1 + \frac{b_1 - a_1}{2}$$

If $f(p_1) = 0$, then $p = p_1$, and we are done.

If $f(p_1) \neq 0$, then $f(p_1)$ has the same sign as either $f(a_1)$ or $f(b_1)$.

o If $f(p_1)$ and $f(a_1)$ have the same sign, $p \in (p_1, b_1)$. Set $a_2 = p_1$ and $b_2 = b_1$.

o If $f(p_1)$ and $f(b_1)$ have opposite signs, $p \in (a_1, p_1)$. Set $a_2 = a_1$ and $b_2 = p_1$. Then reapply the process to the interval $[a_2, b_2]$

Bisectional method steps:

① check $f(a), f(b)$ [opposite in sign]

② $P_1 = \frac{a+b}{2}$

③ $f(P_1) \rightarrow$ check the sign

* Sign of $f(P_1)$ is the same sign of $f(a)$ then replace a by P_1 $P_2 = \frac{P_1+b}{2}$ new interval $[P_1, b]$

* else if the sign of $f(P_1)$ is the same as sign of $f(b)$ then replace b by P_1 $P_2 = \frac{a+P_1}{2}$, new interval $[a, P_1]$

④ $f(P_2)$ check the sign and do the same as step 3 till the P number given to stop
